SUBSTITUTED PYRIDINES AND BIPHENYLS AS ANTI-HYPERCHOLESTERINEMIC, ANTI-HYPERLIPOPROTEINEMIC AND ANTI-HYPERGLYCEMIC AGENTS

### **Field**

5 This application relates to substituted biaryl compounds which inhibit cholesterol ester transfer proteins (CETPs), stimulate reverse cholesterol transport, and inhibit the action of glucagon.

### **Background**

10 The present invention concerns certain substituted pyridines, processes for the production thereof, and the use thereof in pharmaceutical products. It also concerns certain substituted biphenyls, processes for their production, pharmaceutical compositions containing them, and methods for their use.

15 7-(polysubstituted pyridyl) hept-6-enoates for the treatment of arteriosclerosis, lipoproteinemia, and hyperlipoproteinemia are known from US 169 857. In addition, the production of 7-(4-aryl-3-pyridyl)-3,5-dihydroxy-hept-6-enoate is described in EP 325 130.

20 Glucagon is a peptide hormone whose main function is to increase hepatic glucose production. Insulin, on the other hand, functions to decrease glucose production. Together, these two hormones are necessary for maintaining a correct level of glucose in the blood.

25 Diabetes is a complex disease characterized by hyperglycemia resulting from defects in insulin secretion, insulin action, or both. Diabetes is also associated with elevated glucagon levels. The heterogeneous nature of the disease requires different strategies to address the different abnormalities in metabolism found in affected individuals.

30 In the diabetic state (all forms of Type I and Type II), hyperglycemia often is associated with elevated glucagon levels. Accordingly, a means of treating all forms of diabetes is to block the glucagon receptor with a suitable antagonist, thereby inhibiting glucose production by the liver and reducing glucose levels in the patient.

Glucagon receptor antagonists, materials which block the action of endogenous glucagon, are known to have many and varied applications. Among these applications are the following:

- 0        1. Treatment of hyperglycemia associated with diabetes of any cause and associated with any other diseases or conditions. A glucagon receptor antagonist can be used either alone or in combination with any other therapies to treat hyperglycemia.
2. Treatment of impaired glucose tolerance (IGT).
- 5        3. Treatment of insulin resistance syndromes including those due to obesity, polycystic ovarian syndrome, "Syndrome X", drugs and hormones, endocrinopathies and genetic syndromes.
4. To decrease free fatty acid levels and treat conditions associated with elevated free fatty acids levels such as insulin resistance, obesity, all or part of
- 10        Syndrome X, Type I and II diabetes, hyperlipidemias and elevated hepatic glucose output associated with insulin resistance, Type I and Type II diabetes, obesity, and Syndrome X.
5. To treat conditions associated with genetic defects in insulin action due to alterations in insulin receptor structure and function or alterations in post
- 15        receptor signal transduction. To treat diabetes associated with anti-insulin antibodies, drug induced diabetes, diabetes associated with endocrinopathies and diabetes associated with genetic syndromes.
6. To treat gestational diabetes mellitus.
7. To treat autoimmune and non autoimmune causes of Type I diabetes
- 20        including those due to known genetic defects of the beta cell, pancreatic diseases, drug or toxin induced beta cell dysfunction, endocrinopathies, infectious causes, malnutrition associated and idiopathic Type I diabetes.
8. To prevent and treat diabetic ketoacidosis and decrease hepatic ketone body production
- 25        9. To treat hyperglycemia of exercise in diabetes.
10. To reduce fasting and postprandial glucose.
11. Treatment of insulin resistance in liver, muscle, and fat.
12. Treatment of conditions of hyperlipidemia.
13. To treat glucagonomas and all other conditions associated with elevated
- 30        glucagon levels.
14. To treat conditions of increased futile cycling of glucose in the liver.
15. To increase insulin secretion.
16. To decrease glucose toxicity.

- 0           17. To decrease the renal prostaglandin response to protein and amino acids.
18. To decrease elevated GFR and albumin clearance due to diabetes or proteins or amino acids.
19. To decrease renal albumin clearance and excretion.
- 5           20. To treat acute pancreatitis.
21. To treat cardiovascular disease including causes of increased cardiac contractility.
22. To treat cardiac hypertrophy and its consequences.
23. As a diagnostic agent and as a diagnostic agent to identify patients
- 10          having a defect in the glucagon receptor.
24. Treatment of gastrointestinal disorders, treatment of decreased gut motility.
25. As a therapy to increase gastric acid secretions.
26. To reverse intestinal hypomobility due to glucagon administration.
- 15          27. To reverse catabolism and nitrogen loss in states of negative nitrogen balance and protein wasting including all causes of Type I and Type II diabetes, fasting, AIDS, cancer, anorexia, aging and other conditions.
28. To treat any of the above conditions or diseases in post-operative or operative period.
- 20          29. To decrease satiety and increase energy intake.

Glucagon receptor antagonists of the prior art, such as those described in WO9518153-A and references cited therein, are predominantly peptide analogues of glucagon. They are susceptible to the actions of endogenous proteases, may precipitate antibody production and immune reactions and can be difficult and

25          expensive to manufacture. Such peptides are usually unsuitable for oral delivery.

One non-peptide glucagon receptor antagonist has been reported (Collins, et al; *BioMed. Chem Lett.* **1992**, 2, 915-918). This quinoxaline derivative, CP-99,711, was shown to inhibit glucagon binding and glucagon action in rat liver membrane at micromolar concentrations.

30           It would be desirable to have inhibitors of CETP which possess valuable pharmacological properties that are superior to those of the state of the art. Certain of the substituted pyridine compounds of the invention are highly effective

0 inhibitors of cholesterol ester transfer proteins (CETP) and stimulate reverse cholesterol transport. They cause a reduction in LDL cholesterol levels in the blood, while at the same time increasing HDL cholesterol levels. They can therefore be used for the treatment of hyperlipoproteinemia or arteriosclerosis.

5 It would also be desirable to have readily prepared non-peptidic glucagon receptor antagonists which are metabolically more stable than peptidic antagonists of the prior art, and which afford good activity and bioavailability. Certain of the substituted pyridine compounds as well as the substituted biphenyls of the invention are highly effective inhibitors of the glucagon receptor. Accordingly, these compounds may be used to treat glucagon-mediated conditions such as those  
10 listed above.

25

#### **CETP Inhibition Test**

##### **1.   Obtaining CETP**

30       CETP is obtained in partially purified form from human plasma by differential centrifugation and column chromatography and is used for testing. In so doing, human plasma is adjusted with NaBr to a density of 1.21 g per ml and is centrifuged for 18 h at 50,000 rpm at 4°C. The bottom fraction (d > 1.21 g/ml) is applied to a Sephadex® Phenyl-Sepharose 4B (Pharmacia) column, washed with 35 0.15 M NaCl/0.001 M TrisHCl, pH 7.4, and then eluted with dist. water. The CETP-active fractions were pooled, dialyzed against 50 mM Na acetate, pH 4.5, and applied to a CM-Sepharose® (Pharmacia) column. They were then eluted with a

0 linear gradient (0-1 M NaCl). The pooled CETP fractions were dialyzed against 10 mM TrisHCl, pH 7.4, and were then further purified by chromatography over a Mono Q® column (Pharmacia).

## 2. Obtaining Radioactively Tagged HDL

5 50 ml of fresh human EDTA plasma was adjusted with NaBr to a density of 1.12 and centrifuged at 4°C for 18 h at 50,000 rpm in the Ty 65 rotor. The upper phase was used to obtain cold LDL. The lower phase was dialyzed against 3x4 l of PDB buffer (10 mM Tris/HCl, pH 7.4, 0.15 mM NaCl, 1 mM EDTA, 0.02% NaN<sub>3</sub>).  
10 20 µl 3H cholesterol (Du Pont NET-725; 1 µCi/µl dissolved in ethanol) was subsequently added per 10 ml of dialysis residue volume and incubated for 72 h at 37°C under N<sub>2</sub>.

The sediment was then adjusted with NaBr to a density of 1.21 and  
15 centrifuged in the Ty 65 rotor for 18 h at 50,000 rpm at 20°C. The upper phase was obtained and the lipoprotein fractions were purified by gradient centrifugation. In so doing, the isolated, tagged lipoprotein fraction was adjusted with NaBr to a density of 1.26. Every 4 ml of this solution was covered in centrifuge tubes (SW 40 rotor) with 4 ml of a solution with a density of 1.21 and 4.5 ml of a solution with a  
20 density of 1.063 (density solutions from PDB buffer and NaBr) and then centrifuged for 24 h at 38,000 rpm and 20°C in the SW 40 rotor. The intermediate layer between the densities 1.063 and 1.21 that contained the tagged HDL was dialyzed against 3x100 volumes of PDB buffer at 4°C.

The dialysis residue contained radioactively tagged <sup>3</sup>H-CE-HDL, which was  
25 adjusted to approx. 5x10<sup>6</sup> cpm per ml and used for the test.

## 3. Conducting the Test

In order to test the CETP activity, the transfer of <sup>3</sup>H cholesterol ester from  
30 human HD lipoproteins to biotinylated LD lipoproteins was measured.

The reaction was ended by adding Streptavidin-SPA® beads (Amersham), and the transferred radioactivity was determined directly in the liquid scintillation counter.

In the test batch, 10 µl HDL-<sup>3</sup>H cholesterol ester (= 50,000 cpm) was  
35 incubated for 18 h at 37°C with 10 µl biotin-LDL (Amersham) in 50 mM HEPES / 0.15 m NaCl / 0.1% bovine serum albumin / 0.05% NaN<sub>3</sub>, pH 7.4, with 10 µl CETP (1 mg/ml) and 3 µl solution of the substance to be tested (dissolved in 10% DMSO /

- 0 1% BSA). Then 200  $\mu$ l of the SPA-Streptavidin bead solution (Amersham TRKQ 7005) was added, and the mixture was further incubated for 1 h under agitation and subsequently measured in the scintillation counter. Corresponding incubations with 10  $\mu$ l buffer, 10  $\mu$ l CETP at 4°C, and 10  $\mu$ l CETP at 37°C served as controls.

- 5 The transferred activity in the control batches with CETP at 37°C was assessed as 100% transfer. The substance concentration in which this transfer was reduced by half was indicated as an IC<sub>50</sub> value.

CETP inhibitory activity of the following compounds:

Example No.	IC <sub>50</sub> ( $\mu$ M)

- Syrian golden hamsters from the company's own breeding were anesthetized after fasting for 24 h (0.80 mg/kg atropine, 0.80 mg/kg Ketavet<sup>®</sup> s.c., 30' later 50 mg/kg Nembutal i.p.). The jugular vein was then exposed and cannulated. The test substance was dissolved in a suitable solvent (as a rule, Adalat placebo solution: 60 g glycerin, 100 ml H<sub>2</sub>O, ad 100 ml PEG-400) and administered to the animals via a PE catheter inserted into the jugular vein. The control animals received the same volume of solvent without any test substance. The vein was then ligated and the wound closed up. At different intervals — up to 24 hours after administration of the test substance — blood was drawn from the animals by puncture of the retroorbital venous plexus (approx. 250  $\mu$ l). Coagulation was completed by incubating at 4°C overnight, then the blood was centrifuged for 10 minutes at 6000 g. The cholesterol and triglyceride content in the serum obtained in this manner was determined using modified commercially available enzyme tests (cholesterol enzymatic 14366 Merck, triglyceride 14364 Merck). The serum was diluted in a suitable manner with physiological saline solution.
- 20
- 25

- 100  $\mu$ l serum dilution was mixed with 100  $\mu$ l test substance in 96-hole perforated plates and incubated 10 minutes at room temperature. The optical density was then determined with an automatic plate reader at a wavelength of 492 nm (SLT-Spectra). The triglyceride/cholesterol concentration contained in the samples was determined using a parallel-measured standard curve.
- 30

0       The determination of the HDL cholesterol content was carried out after precipitation of the lipoproteins containing Apo B by means of a reagent mixture (Sigma 352-4 HDL cholesterol reagent) according to the manufacturer's instructions.

5       In attempting to determine oral efficacy, the test substance, which was dissolved in DMSO and suspended in 0.5% methylcellulose, was administered orally to Syrian golden hamsters from the company's own breeding via a pharyngeal tube. The control animals received identical volumes of solvent without any test substance. Feed was then withheld from the animals and blood was drawn at  
10 different intervals — up to 24 hours after administration of the substance — via puncture of the retroorbital venous plexus. It was further processed as described above.

15       The new active compounds can be converted in a known manner into the customary formulations, such as tablets, coated tablets, pills, granules, aerosols, syrups, emulsions, suspensions, and solutions, using inert, non-toxic, pharmaceutically suitable excipients or solvents. In this connection, the therapeutically active compound should be present in each case in a concentration of about 0.5% to 90% by weight, i.e., in amounts that are sufficient to achieve the  
20 dosage range indicated.

      The formulations are prepared, for example, by extending the active compounds using solvents and/or excipients, if appropriate using emulsifiers and/or dispersants, where, for example, in the case of the use of water as a diluent,  
25 organic solvents can be used, if appropriate, as auxiliary solvents.

      The administration takes place in a customary manner, preferably orally or parenterally, in particular, perlingually or intravenously.

30       In the case of parenteral use, solutions of the active compound can be employed using suitable liquid excipients.

      In general, it has proved advantageous in intravenous administration to administer amounts of about 0.001 to 1 mg/kg, preferably about 0.01 to 0.5 mg/kg  
35 of body weight, to attain effective results, and in oral administration, the dosage is about 0.01 to 20 mg/kg, preferably 0.1 to 10 mg/kg of body weight.

- 0 In spite of this, it may be necessary to deviate from the amounts mentioned, depending on the body weight or the type of administration route, individual behavior toward the medication, the type of formulation thereof, and the time or interval at which administration takes place. Thus, in some cases it may be sufficient to manage with less than the minimum amount previously mentioned,
- 5 whereas in other cases the upper limit mentioned must be exceeded. If larger amounts are administered, it may be advisable to divide these into several individual doses over the day.

### CETP Inhibition Test

#### 1. Obtaining CETP

30

CETP was obtained in partially purified form from human plasma by differential centrifugation and column chromatography and was used for testing. In so doing, human plasma was adjusted with NaBr to a density of 1.21 g/ml and was centrifuged for 18 h at 50,000 rpm at 4°C. The bottom fraction ( $d > 1.21$  g/ml) was applied to a Sephadex® Phenyl-Sepharose 4B (Pharmacia) column, washed with 0.15 M NaCl/0.001 M Tris HCl, pH 7.4, and then eluted with dist. water. The CETP-active fractions were pooled, dialyzed against 50 mM Na acetate, pH 4.5, and applied to a CM-Sepharose®

35

0 (Pharmacia) column. They were then eluted with a linear gradient (0-1 M NaCl). The pooled CETP fractions were dialyzed against 10 mM Tris HCl, pH 7.4, and were then further purified by chromatography over a Mono Q<sup>®</sup> column (Pharmacia).

5 2. Obtaining radioactively-labeled HDL

50 ml of fresh human EDTA plasma was adjusted with NaBr to a density of 1.12 and centrifuged at 4°C for 18 h at 50,000 rpm in the Ty 65 rotor. The upper phase was used to obtain cold LDL. The lower phase was dialyzed against 3 x 4 l PDB buffer (10 mM Tris/HCl, pH 7.4, 0.15 mM NaCl, 1 mM EDTA, 0.02% NaN<sub>3</sub>). 20 µl of 3H cholesterol (Du Pont NET-725; 1 µCi/µl dissolved in ethanol) was subsequently added per 10 ml of dialysis residue volume and incubated for 72 h at 37°C under N<sub>2</sub>.

The sediment was then adjusted with NaBr to a density of 1.21 and centrifuged in the Ty 65 rotor for 18 h at 50,000 rpm at 20°C. The upper phase was obtained, and the lipoprotein fractions were purified by gradient centrifugation. In so doing, the isolated, tagged lipoprotein fraction was adjusted with NaBr to a density of 1.26. Every 4 ml of this solution was covered in centrifuge tubes (SW 40 rotor) with 4 ml of a solution with a density of 1.21 and 4.5 ml of a solution with a density of 1.063 (density solutions from PDB buffer and NaBr) and then centrifuged for 24 h at 38,000 rpm and 20°C in the SW 40 rotor. The intermediate layer between the density of 1.063 and 1.21 that contained the labeled HDL was dialyzed against 3 x 100 volumes of PDB buffer at 4°C.

The dialysis residue contained radioactively-labeled <sup>3</sup>H-CE-HDL, which was adjusted to approx. 5 x 10<sup>6</sup> cpm per ml and used for the test.

3. Conducting the test

In order to test the CETP activity, the transfer of <sup>3</sup>H cholesterol ester from human HD lipoproteins to biotinylated LD lipoproteins was measured.

The reaction was ended by adding Streptavidin-SPA<sup>®</sup> beads (Amersham), and the transferred radioactivity was determined directly in the liquid scintillation counter.

In the test batch, 10 µl of HDL-<sup>3</sup>H cholesterol ester (~50,000 cpm) was incubated for 18 h at 37°C with 10 µl of biotin-LDL (Amersham) in 50 mM HEPES / 0.15 M NaCl / 0.1% bovine serum albumin / 0.05% NaN<sub>3</sub>, pH 7.4, with 10 µl of CETP (1 mg/ml) and 3 µl solution of the substance to be tested

0 (dissolved in 10% DMSO / 1% BSA). Then, 200  $\mu$ l of the SPA-Streptavidin bead solution (Amersham TRKQ 7005) was added, and the mixture was further incubated for 1 h under agitation and subsequently measured in the scintillation counter. Corresponding incubations with 10  $\mu$ l buffer, 10  $\mu$ l CETP at 4°C, and 10  $\mu$ l CETP at 37°C served as controls.

5 The transferred activity in the control batches with CETP at 37°C was assessed as 100% transfer. The substance concentration in which this transfer was reduced by half was indicated as the IC<sub>50</sub> value.

10 Syrian golden hamsters from the company's own breeding were anesthetized after fasting for 24 h (0.88 mg/kg atropine, 0.80 mg/kg Ketavet® s.c., 30' later 50 mg/kg Nembutal i.p.). The jugular vein was then exposed and cannulated. The test substance was dissolved in a suitable solvent (as a rule, Adalat placebo solution: 60 g glycerin, 100 ml H<sub>2</sub>O, ad 100 ml PEG-400) and administered to the animals via a PE catheter inserted into the jugular vein. The control animals  
15 received the same volume of solvent without any test substance. The vein was then ligated and the wound closed up. At different intervals—up to 24 h after administration of the test substance blood was drawn from the animals by puncture of the retroorbital venous plexus (approx. 250  $\mu$ l). Coagulation was completed by incubating at 4°C overnight, and the blood was then centrifuged for  
20 10 minutes at 6,000 g. The cholesterol and triglyceride content in the serum obtained in this manner was determined using modified commercially-available enzyme tests (cholesterol enzymatic 14366 Merck, triglyceride 14364 Merck). The serum was diluted in a suitable manner with physiological saline solution. 100  $\mu$ l serum dilution was mixed with 100  $\mu$ l of test substance in 96-well plates and  
25 incubated for 10 minutes at room temperature. The optical density was then determined with an automatic plate reader at a wavelength of 492 nm (SLT-Spectra). The triglyceride/cholesterol concentration contained in the samples was determined using a parallel-measured standard curve.

30 The determination of the HDL cholesterol content was carried out after precipitation of the lipoproteins containing Apo B by means of a reagent mixture (Sigma 352-4 HDL cholesterol reagent) according to the manufacturer's instructions.

35 In attempting to determine oral efficacy, the test substance, which was dissolved in DMSO and suspended in 0.5% methylcellulose, was administered orally to Syrian golden hamsters from the company's own breeding via a pharyngeal

0 tube. The control animals received identical volumes of solvent without any test substance. Feed was then withheld from the animals, and blood was drawn at different intervals--up to 24 h after administration of the substance--via puncture of the retroorbital venous plexus. Further processing was carried out as described above.

5

The new active compounds can be converted in a known manner into the customary formulations, such as tablets, coated tablets, pills, granules, aerosols, syrups, emulsions, suspensions, and solutions, using inert, nontoxic, pharmaceutically-suitable excipients or solvents. In this connection, the therapeutically-active compound should be present in each case in a concentration of about 0.5% to 90% by weight, i.e., in amounts that are sufficient to achieve the dosage range indicated.

15 The formulations are prepared, for example, by extending the active compounds using solvents and/or excipients, if appropriate using emulsifiers and/or dispersants, with it being possible, for example, in the case of the use of water as a diluent, to use organic solvents, if appropriate, as auxiliary solvents.

20 Administration takes place in a customary manner, preferably orally or parenterally, in particular, perlingually or intravenously.

In the case of parenteral use, solutions of the active compound can be employed using suitable liquid excipients.

25 In general, it has proved to be advantageous in intravenous administration to administer amounts of about 0.001 to 1 mg/kg, preferably about 0.01 to 0.5 mg/kg of body weight, to obtain effective results, and in oral administration, the dosage is about 0.01 to 20 mg/kg, preferably 0.1 to 10 mg/kg of body weight.

30 In spite of this, it may be necessary to deviate from the amounts mentioned, depending on the body weight or the type of administration route, individual response to the medication, the type of formulation thereof, and the time or interval at which administration takes place. Thus in some cases, it may be sufficient to manage with less than the minimum amount previously mentioned, whereas in other cases, the upper limit mentioned must be exceeded. If larger amounts are administered, it may be advisable to divide these into several individual doses over the day.

- 2.8 g (6.98 mmol) of 1,4-dihydro-2-cyclopentyl-6-ethyl-4-(4-fluorophenyl)pyridine-3,5-dicarboxylic acid-3-methylester-5-ethylester is dissolved in 100 ml of absol. methylene chloride, and after addition of 1.6 g (6.98 mmol) of 2,3-dichloro-5,6-dicyano- p-benzoquinone (DDQ), the mixture is stirred for 1 hour at room temperature. After this, it is drawn off by suction over diatomaceous earth and concentrated in a vacuum. Under argon, 2.1 g (5.26 mmol) of 2-cyclopentyl-6-ethyl-4-(4-fluorophenyl)pyridine-3,5-dicarboxylic acid-3-methylester is dissolved in 50 ml of absol. toluene. 26.6 ml of diisobutyl aluminum hydride (1 M solution in toluene) is added dropwise to this solution at  $-60^{\circ}\text{C}$ . After this, the mixture is stirred for 15 minutes at  $-60^{\circ}\text{C}$ , and the reaction solution is then cooled at  $-30^{\circ}\text{C}$  for 18 h. After heating to  $0^{\circ}\text{C}$ , 50 ml of water is added, and the resulting sediment is drawn off by suction and washed 4 times with 50 ml of ethyl acetate. The aqueous phase is washed with 100 ml of ethyl acetate, and the combined organic phases are shaken out with 150 ml of saturated sodium chloride solution, dried with sodium sulfate, and concentrated in a vacuum. The residue is chromatographed over silica gel (100 g of silica gel, 230-400 mesh, d 3.5 cm, mobile solvent ethyl acetate / petroleum ether 15:85).

- Basic compounds of the invention are generally isolated in the form of their pharmaceutically acceptable acid addition salts derived using inorganic or organic  
20 acids. Examples of such materials are hydrochloric, nitric, sulfuric, phosphoric, formic, acetic, trifluoroacetic, propionic, maleic, succinic, and malonic acids. Compounds of the invention which contain an acidic functionality such as a carboxyl group can be isolated in the form of pharmaceutically acceptable addition salts derived using inorganic or organic bases. The salt forming ion derived from  
25 such bases can be a metal ion such as sodium, potassium, lithium, calcium, magnesium, etc., or an ion of an organic base, such as an ammonium or substituted ammonium ion derived from an amine. Examples of suitable amines for this purpose include ammonia, arylalkylamines such as dibenzylamine and *N,N*-dibenzylethylenediamine, lower alkylamines such as methylamine, *t*-butylamine,  
30 procaine, lower alkylpiperidines such as *N*-ethylpiperidine, cycloalkylamines such as cyclohexylamine or dicyclohexylamine, 1-adamantylamine, benzathine, or salts derived from amino acids such as arginine or lysine.

The present invention also encompasses pharmaceutically acceptable "prodrugs" of the compounds of formula (IC) which form such derivatives. These

0 are typically acylated derivatives of alcohol-containing compounds of the invention, though other types of prodrugs are known. Preparation of such derivatives is within the skill of the art.

The inhibitors of the present invention are contemplated for use in veterinary and human applications. For such applications, the active agent(s) are  
5 employed in pharmaceutical compositions which comprise the active ingredient(s) plus a pharmaceutically acceptable carrier which contains one or more diluents, fillers, binders, or other excipients, depending on the administration mode and dosage form contemplated. Examples of such agents include carriers such as sucrose, lactose, or starch; lubricating agents such as magnesium stearate;  
10 adjuvants, such as wetting agents; excipients such as cocoa butter or suppository wax; emulsifying and suspending agents, and sweetening, flavoring and perfuming agents and buffering agents.

The pharmaceutical compositions of the invention may also include one or more known antidiabetic agents in addition to a compound of structural formula  
15 (IC). Examples of such antidiabetic agents are:  $\alpha$ -glucosidase inhibitors such as acarbose or voglibose, insulin sensitizers such as bromocriptine, thiazolidinediones such as troglitazone, insulin secretagogues such as glimepride, sulfonylureas such as glyburide, GLP-1 and its derivatives such as insulinotropan, amylin and its derivatives such as AC-137, calcitonin, insulin and its derivatives such as HOE-901,  
20 biguanides such as metformin, aldose reductase inhibitors such as tolrestat,  $\beta_3$  agonists such as BTA-243, and hypocholesterolemic agents such as lovastatin.

The method of treating glucagon-mediated conditions by administering a glucagon receptor antagonist of the present invention may be practiced in mammals, including humans, which exhibit such conditions. A typical application is  
25 treatment of diabetes.

The compounds of this invention can be administered by oral, parenteral (e.g., intramuscular, intraperitoneal, intravenous or subcutaneous injection or implant), nasal, vaginal, rectal, sublingual, or topical routes of administration and can be formulated in dosage forms appropriate for each route of administration.

30 Solid dosage forms for oral administration include capsules, tablets, pills, powders and granules. In such solid dosage forms, the active compound is admixed with at least one inert pharmaceutically acceptable carrier such as sucrose, lactose, or starch. Such dosage forms can also comprise, as is normal practice, additional substances other than inert diluents, e.g., lubricating agents such as  
35 magnesium stearate. In the case of capsules, tablets and pills, the dosage forms

- 0 may also comprise buffering agents. Tablets and pills can additionally be prepared with enteric coatings such as the OROS-CT/Osmet™ and PULSINCAP™ systems from ALZA and Scherer Drug Delivery Systems.

Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, the elixirs containing inert diluents commonly used in the art, such as water. Besides such inert diluents, compositions can also include adjuvants, such as wetting agents, emulsifying and suspending agents, and sweetening, flavoring and perfuming agents.

- Preparations according to this invention for parenteral administration include sterile aqueous or non-aqueous solutions, suspensions, or emulsions. Examples of non-aqueous solvents or vehicles are propylene glycol, polyethylene glycol, vegetable oils, such as olive oil and corn oil, gelatin, and injectable organic esters such as ethyl oleate. Such dosage forms may also contain adjuvants such as preserving, wetting, emulsifying, and dispersing agents. Alternatively intramuscular, intraarticular or subcutaneous depot injection with or without encapsulation of the drug into degradable microspheres e.g., comprising poly(DL-lactide-co-glycolide) may be used to obtain prolonged sustained drug release. For improved convenience of the dosage form it may be possible to use an i.p. implanted reservoir and septum such as the Percuseal system available from Pharmacia. Improved convenience and patient compliance may also be achieved by the use of either injector pens (e.g. the NovoPen or Q-pen) or needle-free jet injectors (e.g. from Bioject, Mediject or Becton Dickinson). Prolonged zero-order or other precisely controlled release such as pulsatile release can also be achieved as needed using implantable pumps with delivery of the drug through a cannula into the synovial spaces. Examples include the subcutaneously implanted osmotic pumps available from ALZA, such as the ALZET osmotic pump.

Compositions for nasal or sublingual administration are also prepared with standard excipients well known in the art.

- Compositions for rectal or vaginal administration are preferably suppositories which may contain, in addition to the active substance, excipients such as cocoa butter or a suppository wax.

The compounds of this invention can be manufactured into the above listed formulations by the addition of various therapeutically inert, inorganic or organic carriers well known to those skilled in the art. Examples of these include, but are not limited to, lactose, corn starch or derivatives thereof, talc, vegetable oils, waxes, fats, polyols such as polyethylene glycol, water, saccharose, alcohols, glycerin and the like. The formulations may be sterilized by, for example, filtration through a

0 bacteria-retaining filter, by incorporating sterilizing agents into the compositions, by irradiating the compositions, or by heating the compositions. They can also be manufactured in the form of sterile solid compositions which can be dissolved in sterile water, or some other sterile injectable medium immediately before use. Various preservatives, emulsifiers, dispersants, flavorants, wetting agents, 5 antioxidants, sweeteners, colorants, stabilizers, salts, buffers and the like are also added, as required to assist in the stabilization of the formulation or to assist in increasing bioavailability of the active ingredient(s) or to yield a formulation of acceptable flavor or odor in the case of oral dosing.

10 The amount of the pharmaceutical composition to be employed will depend on the recipient and the condition being treated. The requisite amount may be determined without undue experimentation by protocols known to those skilled in the art. Alternatively, the requisite amount may be calculated, based on a determination of the amount of target receptor which must be inhibited to treat the condition. An effective amount of active ingredient is generally in the range 0.0001 15 mg/kg to 100 mg/kg of body weight.

20 The treatment method of the invention is not limited to administration of the above-described pharmaceutical composition. Rather, this treatment regimen may be employed in combination with conventional treatments of diabetes (both Type I and Type II) or of other conditions which are sometimes found in diabetic subjects. Thus, for example, treatment may be administered in conjunction with (a) diet restrictions and exercise; (b) insulin, or other drugs used to treat ketoacidosis; (c) any drug used for the treatment of hyperlipidemia, such as lovastatin, or cardiovascular disease, such as enalapril; (d) drugs used to treat diabetic 25 complications, such as epalrestat and (e) drugs that lower body weight, such as dexfenfluramine.

30 The glucagon receptor antagonists of the invention are useful not only for treatment of the pathophysiological conditions discussed above, but are also useful in other applications such as a diagnostic agent. For example, these compounds can be administered to humans *in vivo* in the fasting state as a diagnostic tool to directly determine whether the glucagon receptor is functional. Serum samples taken before and after such administration can be assayed for glucose levels; comparison of the amounts of blood glucose in each of these samples would be a means for directly determining the ability of the patient's glucagon receptor to

- 0 modulate hepatic glucose output. Alternatively, compounds of the present invention may be useful for finding new glucagon antagonists. For example, a binding assay employing a radiolabeled derivative (such as  $^3\text{H}$ ) of a compound of formula (IC) would be useful in identifying new compounds that competitively bind to the glucagon receptor. Such an assay is useful in identifying structurally
- 5 novel antagonists that may offer advantages in ease of chemical modification, selectivity and oral bioavailability.

- 0 The compounds of the present invention may contain asymmetric centers on the molecule, depending upon the nature of the various substituents. Each such asymmetric center will produce two optical isomers. In certain instances, asymmetry may also be present due to restricted rotation about the central bond adjoining the two aromatic rings of the specified compounds. For example, for
- 5 certain compounds of Formula (IC) wherein Ar is taken as substituted phenyl, there exist additional isomers due to restricted rotation about the central aryl-aryl bond, depending on the substitution pattern.

- 10 It is intended that all isomers, either by nature of asymmetric centers or by restricted rotation as described above, as separated, pure or partially purified isomers or racemic mixtures thereof, be included within the ambit of the instant invention. In the case of compounds of Formula (IC) wherein R<sup>3</sup> is taken as 1-hydroxyethyl, it has been found that the isomer in which the hydroxy substituent is
- 15 above the plane of the structure, as seen in Formula Ic, is more active and thus more preferred over the compound in which the hydroxy substituent is below the plane of the structure.

The compounds of general formula (IC) of the present invention are prepared as indicated in the following reaction Schemes.

15        The phenylpyridine compounds of formula (IC) (X= N) are prepared from a common intermediate 6 using the well-known Hantzsch pyridine synthesis, as shown in Scheme 1 (Stout, D. M.; Myers, A. I. *Chem. Rev.* **1982**, 223).

## SCHEME 1

The ketoester 1, (commercially available or prepared according to the procedure of Deslongchamps, *Synth. Comm.*, **1976**, *6*, 169) is treated with an ammonium salt such as ammonium acetate, in an inert solvent such as cyclohexane capable of forming an azeotrope with water, to give the enamine 2. Compound 2 is then treated with the ketoester 3, which may or may not be identical to the ketoester 1, and an aromatic aldehyde, in a polar solvent such as ethanol, to produce the dihydropyridine 5. Certain substituents on aldehyde 4 may need to be protected during the Hantzsch pyridine synthesis. A description of suitable protecting groups may be found in: Protective Groups in Organic Synthesis, Second Edition, T. W. Greene, John Wiley and Sons, New York, **1991**. Oxidation of 5 is achieved by any of several known methods. For example, treatment of 5 with 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ) in a solvent such as methylene chloride ( $\text{CH}_2\text{Cl}_2$ ), or with ceric ammonium nitrate (CAN) in a mixture of solvents such as aqueous acetone, affords the intermediate 6. Separation of unwanted side products and purification of intermediates is achieved by chromatography on silica gel, employing flash chromatography (Still, W.C.; Khan, M.; Mitra, A. *J. Org. Chem.*, **1978**, *43*, 2923)

An alternative Hantzsch pyridine synthesis of the intermediate **6**, where R<sup>1a</sup> and R<sup>1b</sup> of formula (IC) are identical, can be accomplished following the procedure of Chucholowski (U.S. Patent 4,950,675), Scheme 2. By heating two equivalents of ketoester **1** with ammonium hydroxide and the aldehyde **4** in a polar solvent such as methanol, the dihydropyridine **5** is obtained directly. Compound **5** is oxidized to pyridine **6**, according to the procedure described in Scheme 1.

0

SCHEME 2

In Scheme 3, another alternative Hantzsch pyridine synthesis of intermediate **6** is described. Ketoester **1** is condensed with aldehyde **4** by treatment with catalysts such as acetic acid and piperidine without solvent to afford intermediate **7**. Treatment of **7** with ketoester **3** in the presence of a base such as sodium methoxyde, in a polar solvent such as methanol produces the diketone **8**. Cyclization of **8** is achieved by treatment with an ammonium salt such as ammonium acetate in a polar solvent such as acetic acid to afford the previously described dihydropyridine **5** (Scheme 1), which is oxidized to the pyridine **6** according to the procedure as indicated in Scheme 1.

The synthesis of aryl pyridine derivatives of formula (IC) wherein R<sup>2</sup> is alkyl and R<sup>3</sup> is hydroxymethyl (IIa) is described in Scheme 4.

## SCHEME 4

Chemical reducing agents such as sodium bis(2-methoxyethoxy)aluminum hydride (Red-Al) in an inert solvent, such as tetrahydrofuran (THF) or diethyl ether ( $\text{Et}_2\text{O}$ ), can result in a monoreduction of the pyridinediester **6** to give the alcohol **9**. Oxidants such as pyridinium chlorochromate (PCC), in a solvent such as  $\text{CH}_2\text{Cl}_2$ , convert compound **9** to the aldehyde **10**. Wittig reaction with compound **10** and an ylide **11a**, in an inert solvent such as THF or  $\text{Et}_2\text{O}$ , affords olefin **12** obtained usually, but not always, as a mixture of *E* and *Z* isomers. The reagent **11a** is prepared from an alkyl triphenyl phosphonium salt, wherein the alkyl group may contain a heteroatom, and a suitable base such as butyllithium or sodium amide, according to known methods (Maercker, A. in *Organic Reactions*, Vol. 14, Ed.; Wiley, New York, 1965, Chapter 3). Olefin **12** is successively treated with a reducing agent such as lithium aluminum hydride (LAH), in an inert solvent such as THF or  $\text{Et}_2\text{O}$ , and hydrogen in the presence of a metal catalyst, such as palladium on carbon, in a polar solvent such as ethanol, to afford compounds of formula IIa. In some of these compounds,  $\text{R}^2$  may contain substituents such as alcohol, acetate, ester, carboxylic acid, and amide. These products can be obtained directly by the procedures of Scheme 4, with or without the use of appropriate protecting groups, or by additional steps familiar to those skilled in the art. For example, a primary alcohol can be converted to a carboxylic acid by standard methods of oxidation,

- 0 such as those described by Eisenbraun (Eisenbraun, E. J. *Org. Syn. Coll.*, 1973, 5, 310).

If the Wittig reaction is performed with methoxymethyl triphenylphosphonium as ylide (**11b**), followed by treatment with an acid such as hydrochloric acid, the homologous aldehyde **13** is obtained. This can undergo another Wittig reaction to afford olefin **14**, (Scheme 5). This known procedure (Wittig, G.; Walter, B.; Kruck, K.-H. *Chem. Ber.* 1962, 2514) allows one to synthesize extended alkyl chain ( $R^2$ ) analogs of formula IIa, which may not be directly prepared by usual Wittig reaction due to limited availability of the requisite alkyl triphenylphosphonium salt.

10 Oxidation of the compounds of formula IIa by the method described in Scheme 4 affords intermediates that can be converted to homologues of compounds of formula IIa, containing the  $-CH_2-CH_2-$  linkage between the pyridine nucleus and the hydroxy group (**IIb**).

# 15 SCHEME 5

20 Synthesis of aryl pyridine derivatives of formula (IC) wherein  $R^2$  is alkyl containing a heteroatom such as sulfur and  $R^3$  is hydroxymethyl (**IIIa** and **IIIb**), is outlined in Scheme 6. Alcohol **9** is converted to an alkyl halide **15** by treatment with a suitable reagent such as dibromotriphenylphosphorane in an inert solvent. Treatment of **15** with a thiol and a base such as N-methyl morpholine in an inert solvent produces intermediate **16**. The sulfur atom of compounds **16** can be oxidized ( $n = 1$  or  $2$ ) by any of several known methods. For example, it can be accomplished by treatment of **16** wherein  $n=0$ , with an oxidant such as m-chloroperbenzoic acid in a solvent such as  $\text{CH}_2\text{Cl}_2$ . Chemical reducing agents such

- 0 as lithium aluminum hydride (LAH) in an inert solvent such as tetrahydrofuran or diethyl ether, can reduce the ester 16 to a compound of formula IIIa. Intermediate 15 can also react with alcohols following the methods outlined in Scheme 6, to afford compounds of formula IIIc.

5

## SCHEME 6

- The synthesis of aryl pyridine derivatives of formula (IC) wherein R<sup>2</sup> is alkyl containing a heteroatom such as nitrogen and R<sup>3</sup> is hydroxymethyl (IVa), is outlined in Scheme 7. Treatment of 15 with a primary or secondary amine in an inert solvent results in the intermediate 17. Chemical reducing agents such as lithium aluminum hydride in an inert solvent, such as tetrahydrofuran or diethyl ether, can reduce ester 17 to a compound of formula IVa. Reduction of aldehyde 13 by the method outlined in Scheme 4 affords an intermediate that can be converted to homologues of compounds of formula IIIa and IVa, containing the -CH<sub>2</sub>-CH<sub>2</sub>- linkage between the pyridine nucleus and the sulfur or nitrogen substituent (IIIb and IVb).

## SCHEME 7

Synthesis of aryl pyridine derivatives of formula (IC) wherein R<sup>2</sup> is alkyl and R<sup>3</sup> is 1-hydroxyethyl (Va), is outlined in Scheme 8. Oxidants such as pyridinium chlorochromate (PCC), are used to convert compounds of formula II to the aldehyde 18. Treatment of 18 with an organometallic reagent such as methyl magnesium bromide or methyl lithium in an inert solvent such as THF or Et<sub>2</sub>O affords racemic compounds of formula Va. Chiral 1-hydroxyethyl aryl pyridine derivatives of formula Vb are obtained by resolution of the racemates Va by classical methods. For example, resolution can be achieved by formation of diastereomeric adducts of the racemic compounds with optically active reagents such as  $\alpha$ -methoxy- $\alpha$ -(trifluoromethyl)phenylacetic acid (Dale, J.A.; Dull, D.L.; Mosher, H.S. *J. Org. Chem.* **1969**, *34*, 2543). Alternatively, separation of enantiomers is achieved by HPLC on chiral solid phase. Determination of absolute stereochemistry can be achieved in a number of ways familiar to those skilled in the art, including X-ray analysis of a suitable crystalline derivative, such as a Mosher ester.

## SCHEME 8

20

0

An alternative synthesis of aryl pyridine derivatives of formula Vb is achieved by treating aldehyde 18 with the anion of methyl toluylsulfoxide 19 to give a diastereomeric mixture of alcohols 20 as shown in Scheme 9 (Blase, F. R.; Le H. *Tet. Lett.* 1995, 36, 4559). The diastereomers are separated by flash chromatography and treated separately with Raney nickel and hydrogen in ethanol to provide pure enantiomers (>99% enantiomeric excess, e.e.) of the compounds of formula Vb. Alternatively, the chromatographic step is avoided by a two step sequence consisting of (1) oxidation of the mixture 20 with manganese dioxide in an inert solvent, followed by (2) reduction of the ketone with a chemical reductant such as LAH, to provide the enantiomerically pure alcohol 21. Treatment of 21 with Raney nickel and hydrogen in a polar solvent provides pure enantiomer (>99% e.e.) of the compounds of formula Vb.

## SCHEME 9

15

A preferred alternative enantioselective synthesis of aryl pyridine derivatives of formula Vb is shown in Scheme 10. Treatment of the racemic mixture of compounds of formula Va with an oxidant such as pyridinium chlorochromate (PCC), gives the ketone 22. Reduction of 22 with a complex of LAH and N-methylephedrine (Kawasaki, M.; Susuki, Y.; Terashima, S. *Chem. Lett.* 1984, 239) in an inert solvent, provides the alcohol of formula Vb with an enantiomeric excess of 95%.

## SCHEME 10

The synthesis of aryl pyridine derivatives of formula (IC) wherein  $R^2$  is alkyl and  $R^3$  is 1,2-dihydroxyalkyl (VI), is described in Scheme 11. A methyl triphenylphosphonium salt is treated with a suitable base such as butyllithium in an inert solvent and reacted with intermediate 18 to afford olefin 23. Treatment of compound 23 with a suitable oxidant such as osmium tetroxide in a polar solvent such as pyridine gives the compounds of formula VI.

## SCHEME 11

The synthesis of aryl pyridine derivatives of formula (IC) wherein  $R^2$  and  $R^{1b}$  are taken together to form an alkylene bridge and  $R^3$  is hydroxymethyl (VIIa), is described in Scheme 12. The ketoester 1, is treated with an aromatic aldehyde and catalysts such as acetic acid and piperidine, in ethanol, to afford the  $\alpha,\beta$ -unsaturated ketoester 24. Treatment of 24 with the cyclic ketone 25 and a base such as lithium bis(trimethylsilyl)amide in an inert solvent such as THF affords an intermediate which is treated with ammonium acetate and copper acetate in acetic

- acid to give the pyridine 26. Chemical reducing agents reduce the ester 26 to analogs of formula VIIa. It may be appreciated that these analogs can be used as intermediates to generate new derivatives of formula (IC) wherein R<sup>2</sup> and R<sup>1b</sup> are taken together and R<sup>3</sup> is 1-hydroxyethyl (VIIb) according to the procedures described in Scheme 8.

The biphenyl analogs described in formula (IC) ( $X = \text{C-R}^8$ , wherein  $\text{R}^8$  is H), are prepared by the methods described by Fey, *et al.* US Patent 5,138,090. The key step of the synthesis is the coupling of an arylpalladium dimer with an aryl Grignard reagent (Scheme 23).

10

### SCHEME 23

15 A specific example of this method is shown in Scheme 24. Treatment of diol 43 (prepared according to the procedure of Fey, *et al.* US Patent 5,138,090) with (2-methoxy)ethoxymethyl chloride and diisopropylethylamine in  $\text{CH}_2\text{Cl}_2$  solvent gives MEM ether 44. Oxidation of the remaining alcohol of 44 as described in Scheme 4 provides aldehyde 45. Treatment of the aldehyde with aniline in the presence of a catalytic amount of p-toluenesulfonic acid (pTSA) and molecular sieves in toluene solvent gives imine 46. The imine is converted to the palladium dimer 47 upon treatment with palladium acetate in acetic acid solvent. Treatment of 47 with triphenylphosphine, then with 4-fluorophenylmagnesium bromide

The aldehyde moiety of biphenyl **48** is converted to a pentyl group by the methods described in Scheme 4. MEM ether **50** is treated with trimethylsilyl chloride and sodium iodide in acetonitrile solvent, and subsequently with sodium acetate in DMF solvent to

SCHEME 24

10

An alternative synthesis of biphenyls of formula (IC) is the coupling of a suitably functionalized benzene derivative 57 (where X can be trifluoromethanesulfonate, methoxy, bromide, or iodide) with an arylmetal reagent ArMY<sub>n</sub> (where M may be B, Sn, or Mg, and Y is a ligand).

SCHEME 27

10

A specific example of the use of the Suzuki reaction to synthesize a biphenyl analog is depicted in Scheme 28. Phenol 61 is treated sequentially with sodium hydride and allyl bromide in dimethylformamide solvent to afford allyl ether 62. Claisen rearrangement of the ether provides phenol 63. The phenol is treated with trifluoromethanesulfonic anhydride (triflic anhydride) and pyridine in CH<sub>2</sub>Cl<sub>2</sub> solvent to give triflate 64. Treatment with 4-fluorophenylboronic acid, tetrakis(triphenyl)phosphine palladium (0), potassium phosphate (tribasic), and potassium bromide in 1,4-dioxane solvent affords biphenyl 65. Catalytic hydrogenation as described in Scheme 4, and reduction of the ketone with lithium aluminum hydride in THF solvent provides the desired biphenyl analog 67.

20

SCHEME 28

25

An alternative synthesis of biphenyls of type I uses a cycloaromatization of a ketodiester 68 with a diketone in the presence of a catalytic amount of sodium methoxide in methanol solvent to give a phenol 69. The phenol is then coupled with an arylboronic acid as described in Scheme 28 to afford biphenyl diester 70. The diester is then transformed as described in Schemes 4, 8, and 10 to give the analog with the desired  $\text{R}^2$  and  $\text{R}^3$  groups.

#### SCHEME 29

An alternative method of transforming phenol 69 to biphenyl 70 is shown in Scheme 30. Treatment of the phenol with dimethylsulfate and a base such as potassium carbonate yields the methyl ether 71. The ether is treated with an aryl Grignard reagent to afford biphenyl 70.

## SCHEME 30

- 5 The diester 70 can be further transformed by an alternative method shown in Scheme 31, to give the analogs with the desired R<sup>2</sup> and R<sup>3</sup> groups. Chemical reducing agents such as sodium bis-(2-methoxyethoxy)-aluminum hydride (Red-Al), can result in a mono reduction of the diester 70 to give the alcohol 72. Alcohol 72 can be attached to a polymeric support such as Wang resin, by treatment with a base such as sodium hydride in DMF, to give the intermediate 73. The ester group of intermediate 73 can be transformed to an alkyl halide in a two step process; 73 is treated with a reducing agent such as LAH, then Phosphorous tribromide to afford compound 74. The alkyl halide 74 is treated with an alkyl thiol and a base such as N-methyl morpholine, then by TFA to cleave the ether linkage with the polymeric resin, to afford the alcohol 75.

## SCHEME 31

0 It will be appreciated that synthesis of some compounds of formula (IC) may require use of protecting groups at various stages of the procedures. These are removed in subsequent steps. For example, the removal of O-benzyl ether protecting groups is carried out by treatment with hydrogen in the presence of a metal catalyst, such as palladium on carbon, in a polar solvent such as ethanol. The removal of silyl ether protecting groups is carried out by treatment with fluoride salts, such as tetrabutylammonium fluoride in a solvent such as THF. Conditions required to remove other protecting groups which may be present can be found in: Protective Groups in Organic Synthesis, Second Edition, T. W. Greene, John Wiley and Sons, New York, 1991.

10 The order of carrying out the steps of the foregoing reaction schemes is not always significant, and it is within the skill of the art to vary the order of reactions to facilitate the reaction or to avoid unwanted reaction products.

15 The following examples are provided for the purpose of further illustration only and are not intended to limit the disclosed invention.

#### EXAMPLE 1

#### 2,6-Diisopropyl-3-hydroxymethyl-4-(4-fluorophenyl)-5-pentylpyridine

##### Step A: 3-Amino-4-methyl-2-pentenoic acid, ethyl ester

To 100 g (0.63 mol) of ethyl isobutyryl acetate was added ammonium acetate (68.2 g, 0.89 mol), cyclohexane (230 mL) and isopropanol (74 mL). The mixture was heated at reflux under argon atmosphere with a Dean-Stark trap. After 2 hours, a second portion of ammonium acetate (14.6 g, 0.19 mol) was added to the reaction.

30 The reaction was heated at reflux for 12 hours and then allowed to cool to room

0 temperature. A total of ~30 mL of water was collected in the Dean-Stark trap. An ice bath was used to cool the reaction to 10°C and then ammonium hydroxide (63 mL) was added dropwise. The organic layer was separated, dried with sodium sulfate, filtered, and concentrated to yield a yellow oil. The crude product (90.9 g, 0.58 mol, 92%) was taken directly to the next step without any further purification.

5 Step B: Diethyl 1,4-dihydro-2,6-diisopropyl-4-(4-fluorophenyl)-3,5-pyridinedicarboxylate

To ethyl 3-amino-4-methylpent-2-enoate (Step A) (90 g, 57 mmol) was added ethyl isobutyryl acetate (90g, 57 mmol) and 4-fluorobenzaldehyde (61.4 mL, 0.57 mmol). The mixture was heated under argon at 130°C for 26 hours (Precaution: Check the reflux condenser after a few hours as excess ammonium acetate will clog the condenser). The reaction was allowed to cool to room temperature and left to crystallize for 4 days. The solid was collected by filtration with vacuum (46.9 g, 116 mmol, 20%) and taken directly to the next step without further purification.

15 Step C: Diethyl 2,6-diisopropyl-4-(4-fluorophenyl)-3,5-pyridinedicarboxylate

To the intermediate obtained in Step B (33 g, 82 mmol) in dichloromethane (400 ml) was added 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ, 20.5 g, 90 mmol) under argon and the mixture was stirred for 2 hours. The stirring was stopped to allow the precipitate to settle. The precipitate was filtered, washed with dichloromethane (3 x 30 mL), and discarded. The filtrate was concentrated to afford a brown solid, which was subjected to flash chromatography (6/4 mixture of dichloromethane/hexanes) resulting in a pure white solid (25.8 g, 64.3 mmol, 78%).  
25 <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 7.28 (m, 2 H), 7.06 (m, 2 H), 4.03 (q, J = 7.0 Hz, 4 H), 3.11 (septet, J = 6.6 Hz, 2 H), 1.32 (d, J = 6.5 Hz, 12 H), 0.979 (t, J = 3.3 Hz, 6 H). FAB-MS: calculated for (C<sub>23</sub>H<sub>28</sub>NO<sub>4</sub>F) 401, found 402 (M+H). Anal. calc for C<sub>23</sub>H<sub>28</sub>NO<sub>4</sub>F: C, 68.64; H, 7.24; N, 3.48; F, 4.72. Found: C, 69.12; H, 6.98; N, 3.42; F, 4.96. mp 72-74°C. R<sub>f</sub>=0.4 (10% ethyl acetate/hexane).

30 Step D: Ethyl 2,6-diisopropyl-4-(4-fluorophenyl)-5-hydroxymethyl-3-pyridinecarboxylate

To a solution of the intermediate obtained in Step C (23.4 g, 58.3 mmol) in anhydrous tetrahydrofuran (300 mL) stirred under argon at 0°C was added a solution of 3.4M of sodium bis(2-methoxyethoxy)aluminum hydride in toluene (Red-Al) (61 mL, 204 mmol, 65 wt% in toluene) via syringe over 20 min. The reaction mixture was allowed to stir at room temperature for 7 hr, then cooled

- 0 again to 0°C and carefully quenched by the dropwise addition of water. The solution was decanted from the solid which forms and the solvent removed *in vacuo*. The residue was purified by flash chromatography (300 g silica) via step gradient. Elution with 5% diethyl ether/hexane afforded 6.6 g (16.4 mmol, 28%) of recovered starting material and elution with 40% diethyl ether(Et<sub>2</sub>O)/hexane
- 5 yielded the desired product as a yellow waxy solid (14 g, 39 mmol, 67%). <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 7.27 (m, 2 H), 7.10 (m, 2 H), 4.46 (d, *J* = 5.2 Hz, 2 H), 3.98 (q, *J* = 7 Hz, 2 H), 3.48 (sept, *J* = 6.6 Hz, 1 H), 3.05 (sept, *J* = 6.6 Hz, 1 H), 1.32 (t, *J* = 6.6 Hz, 12 H), 0.97 (t, *J* = 7 Hz, 3 H). FAB-MS: calculated for (C<sub>21</sub>H<sub>26</sub>FNO<sub>3</sub>) 359, found 360 (M+H). *R*<sub>f</sub> = 0.2 (20% ethyl acetate/hexane).

10

Step E: 5-Carboethoxy-2,6-diisopropyl-4-(4-fluorophenyl)-3-pyridinecarboxaldehyde

- To a solution of the intermediate obtained in Step D (13 g, 36 mmol) in dichloromethane (1 L) was added Brockman I neutral alumina (7.4 g, 72 mmol).
- 15 The suspension was stirred at room temperature and treated with pyridinium chlorochromate (PCC) (16 g, 72 mmol) in three portions. The suspension was stirred at room temperature for 1 hr, then poured into 1:1 diethyl ether/hex (1 L), filtered through a pad of silica, the pad washed with diethyl ether (500 mL) and the combined eluent concentrated to afford a viscous oil which slowly solidified (12.8 g,
- 20 35.9 mmol, 99%): *R*<sub>f</sub> = 0.31 (10% ethyl acetate/hexane). <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 9.85 (s, 1 H), 7.27 (m, 2 H), 7.13 (m, 2 H), 4.04 (q, *J* = 7 Hz, 2 H), 3.88 (sept, *J* = 6.6 Hz, 1 H), 3.12 (sept, *J* = 6.6 Hz, 1 H), 1.33 (t, *J* = 6.6 Hz, 12 H), 1.00 (t, *J* = 7 Hz, 3 H). EI-MS calcd for (C<sub>21</sub>H<sub>24</sub>FNO<sub>3</sub>) 357, found 358 (M+H). Anal. Calcd for C<sub>21</sub>H<sub>24</sub>FNO<sub>3</sub>: C, 70.57; H, 6.77; N, 3.92. Found: C, 70.62; H, 6.78; N, 3.84.

25

Step F: Ethyl 2,6-diisopropyl-4-(4-fluorophenyl)-5-(1-pentenyl)-3-pyridinecarboxylate

- Butyltriphenylphosphonium bromide (2.7 g, 6.76 mmol) was suspended in anhydrous THF (75 mL) under argon and stirred at -78°C. A 1.6 M solution of *n*-butyllithium in hexanes (4.2 mL, 6.76 mmol) was added dropwise. The reaction
- 30 mixture was allowed to come to 0°C and was stirred at that temperature for 1.5 hr. The resulting brightly colored solution was cooled again to -78°C and treated dropwise with a solution of the intermediate obtained in Step E (2 g, 5.60 mmol) in THF (20 mL). 2,6-Diisopropyl-3-hydroxymethyl-4-(4-fluorophenyl)-5-[(4-nitrophenyl)thio]methylpyridine

0    Step A:    2,6-Diisopropyl-3-hydroxymethyl-4-(4-fluorophenyl)-5-  
                  [(t-butyldimethylsiloxy)methyl]pyridine

                  A solution of 3 g (8.3 mmol) of methyl 2,6-diisopropyl-4-(4-fluorophenyl)-5-hydroxymethyl-3-pyridinecarboxylate (Example 47, Step A) in anhydrous DMF (75 mL), was treated at room temperature with imidazole (1.3 g, 19 mmol), 4-dimethylaminopyridine (50 mg, 0.4 mmol) and t-butyldimethylsilyl chloride (1.4 g, 9.3 mmol). The reaction mixture was allowed to stir at room temperature for 48 hr. The solution was diluted with diethyl ether (200 mL) and washed with water (2 x 100 mL), 1N HCl (100 mL), sat. NaHCO<sub>3</sub> (50 mL) and brine (100 mL), dried (MgSO<sub>4</sub>) and concentrated to 4 g as an oil: R<sub>f</sub> = 0.4 (10% ethyl acetate/hexane).

Butyllithium (1.6 M, 0.42 mL) was added dropwise over 2 min. and then the reaction mixture was allowed to stir at 0°C for 1.5 hours. The solution was cooled again to -78°C, treated dropwise with a solution of 2,6-diisopropyl-4-(4-fluorophenyl)-5-pentyl-3-pyridinecarbox-aldehyde (Example 114, Step A) in 5 mL of dry THF, and then stirred at 0°C for 2.5 hours. The reaction was quenched with water (10 mL) and the THF evaporated *in vacuo*. Diethyl ether was added and the mixture was washed with water (2 x 20 mL), brine (1 x 20 mL), and dried with MgSO<sub>4</sub>. Filtration, concentration and flash chromatography (30% CH<sub>2</sub>Cl<sub>2</sub>/hexanes) yielded a solid (0.132 g, 0.37 mmol, 66%). <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>) δ 7.08 (m, J = 1.1 Hz, 4 H), 6.34, 6.28 (d, J = 11.4 Hz, J = 11.4 Hz, 1 H), 5.19 (d, J = 1.8 Hz, 1 H), 4.96 (d, J = 1.8 Hz, 1 H), 3.39 (septet, J = 6.6 Hz, 1 H), 3.24 (septet, J = 6.6 Hz, 1 H), 2.30 (t, J = 5.2 Hz, 2 H), 1.20 (m, J = 2.2 Hz, 18 H), 0.979 (t, J = 6.0 Hz, 3 H). 5 Step A: 3,5-Diisopropyl-2-(1-hydroxyethyl)-6-pentyl-4'-fluoro-1,1'-biphenyl,  
hemi-phthalate ester

A solution of 1.90 g (5.36 mmol) of 3,5-diisopropyl-2-formyl-6-pentyl-4'-fluoro-1,1'-biphenyl (Example 191, Step A) in 36 mL of tetrahydrofuran at -78°C under an argon atmosphere was treated with a dropwise addition of 4.6 mL (6.43 mmol) of a 1.4 M solution of methylolithium in ether. The reaction mixture was allowed to warm to room temperature over one hour. 1.03 g (6.97 mmol) of phthalic anhydride was then added as a solid and stirring was continued for another hour. The reaction was quenched with 30 mL saturated aqueous ammonium chloride and extracted with 60 mL ethyl acetate. Separated organic phase was washed again with 30 mL saturated aqueous ammonium chloride. Combined aqueous portions were extracted with several portions of 20 mL of ethyl acetate. Combined organic portions were dried (Na<sub>2</sub>SO<sub>4</sub>) and concentrated in vacuo. The crude mixture was purified by flash column chromatography on silica using hexanes:ethyl acetate:acetic acid (75:24:1) as eluent to provide 2.55 g (4.94 mmol, 97 %) of the product. FAB-MS: calculated for C<sub>33</sub>H<sub>39</sub>O<sub>4</sub>F 518; found 519 (M+H). <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 0.77 (t, J = 7.0 Hz, 3H), 1.03 - 1.30 (m, 18H), 1.53 (d, J = 7.0 Hz, 3H), 2.16 - 2.22 (m, 2H), 3.05 - 3.20 (m, 1H), 3.53 - 3.65 (m, 1H), 5.87 - 5.93 (m, 1H), 7.05 - 7.37 (m, 4H), 7.54 - 8.06 (m, 5H). 25 Step B: (+)-3,5-Diisopropyl-2-(1-hydroxyethyl)-6-pentyl-4'-fluoro-1,1'-

A solution of 2.54 g (4.90 mmol) of the hemi-phthalate ester from Step A in 50 mL of hexane and 0.5 mL of methanol at reflux was treated with 0.63 mL (4.90 mmol) of (R)-(+)-a-methylbenzylamine. Reflux was continued until solids began to

precipitate. At this point, the flask was removed from the hot plate and allowed to cool. Further cooling was achieved by placing the flask in a freezer (-25°C) overnight. Crystals were harvested via filtration and washed with hexane. The amine salt crystals were then suspended in hexane and methanol was added at reflux until the crystals dissolved. Reflux was continued until solids began to precipitate. At this point, the flask was removed from the hot plate and allowed to cool. Further cooling was not necessary and the salt crystals were harvested as above. The salts were crystallized a third time via the second method described, and the harvested crystals were placed in a vacuum oven overnight at 50°C to afford 0.57 g (0.89 mmol, 18 %) of crystalline amine salt. A solution of 0.57 g (0.89 mmol) of the amine salt in 5 mL dioxane was treated with a 20% solution (w/v) of NaOH/H<sub>2</sub>O and was held at reflux for 3.5 hours. After cooling to room temperature, the reaction mixture was diluted with 20 mL of ethyl acetate. The separated aqueous phase was extracted with ethyl acetate (2 x 10 mL). Combined organic extracts were dried (Na<sub>2</sub>SO<sub>4</sub>) and concentrated in vacuo. A solution of lithium diisopropylamide was prepared by the addition of *n*-butyllithium (15 mL, 23 mmol, 1.6 M/hexane) to a solution of diisopropylamine (3 mL, 23 mmol) in anhydrous tetrahydrofuran (100 mL) at 0 °C. To this was added a

0 solution of (S)-(-)-methyl *p*-tolylsulfoxide (3.6 g, 23 mmol) in anhydrous tetrahydrofuran (20 mL) dropwise, with stirring. The mixture was stirred at 0 °C for 2 hr, then treated with a solution of 2,6-diisopropyl-4-(4-fluorophenyl)-5-propyl-3-pyridinecarboxaldehyde (Example 101, Step A) (3.8 g, 11 mmol) in anhydrous tetrahydrofuran (50 mL) dropwise and with stirring. The organic phase was washed with saturated NaHCO<sub>3</sub> (100 mL), water (100 mL) and brine (50 mL), dried over MgSO<sub>4</sub> and concentrated. The crude product consisted of a 1.3:1 ratio of diastereomers which were separated by flash chromatography (step gradient 5%-15%-20% ethyl acetate/hexane), which afforded 1.5 g of the faster diastereomer (I), followed by 2.7 g of the slower diastereomer (II) and 0.83 g of a mixed fraction. Diastereomer II is recrystallized once from ethanol/hexane to afford fine white needles (1.7 g, 3.5 mmol, 30% yield). 5 Step E: Diisopropyl 3,5-diisopropyl-2'-benzyloxy-4'-fluoro-1,1'-biphenyl-2,6-dicarboxylate

A dry flask containing freshly ground magnesium turnings (2.88 g, 120 mmol) and a crystal of iodine was heated until a dark purple iodine atmosphere had formed. The flask was cooled to ambient temperature and a solution of 2-bromo-5-fluorophenyl benzyl ether (33.8 g, 120 mmol, Example 166, Step A) in dry tetrahydrofuran (60 mL) was added in several portions over 40 minutes at a rate sufficient to maintain reflux. Reflux was continued for 45 minutes, then the reaction was cooled to room temperature. This solution of Grignard reagent was transferred via syringe to a second flask containing a solution of the intermediate from Step D (11.0 g, 30.2 mmol) in dry benzene (66 mL). The reaction mixture was held at reflux for one hour, quenched with 10% aqueous hydrochloric acid (300 mL) and extracted with diethyl ether (3 x 300 mL). The combined extracts were dried over magnesium sulfate and concentrated in vacuo to give a brown oil which was subjected to flash column chromatography on silica (80 mm x 19.5") using a stepwise gradient elution of dichloromethane:hexanes (1:3, 1:2, 1:1, 4L each). The fractions containing the product were combined and concentrated to afford an inseparable mixture of the product and an unidentified side product in about a 1:1 ratio as a pale yellow gum (5.3 g, 33% mass balance). This material was not fully characterized and was used without further purification.

Step F: Isopropyl 3,5-diisopropyl-6-hydroxymethyl-2'-benzyloxy-4'-fluoro-1,1'-biphenyl-2-carboxylate

A mixture of the intermediate from Step E (5.83 g, 10.9 mmol) and Red-Al (3.3 mL, 10.9 mmol) in dry tetrahydrofuran (100 mL) was held at reflux for 2.5 hours. Additional Red-Al was added (in 3.3 mL aliquots) and reflux maintained until the lower  $R_f$  spot disappeared (21 hours, total 8 eq. Red-Al; i.e. the by-product from the previous step reacted faster than the desired diester). The reaction mixture was cooled to 0 °C, carefully quenched with water (14 mL), and vigorously stirred for 2 hours. The precipitated solids were removed via vacuum filtration through paper and the collected solids were washed with ethyl acetate (3 x 100 mL) and refiltered. The combined filtrates were washed with a 1:1 mixture of water and saturated aqueous sodium chloride (100 mL), followed by water (75 mL) and

Purification by flash column chromatography on silica (80 mm x 6") using hexanes:ethyl acetate (19:1) as eluent gave pure diisopropyl 3,5-diisopropyl-2'-benzyloxy-4'-fluoro-1,1'-biphenyl-2,6-dicarboxylate (2.63 g, 4.92 mmol). This was resubjected to the reaction conditions with Red-Al (2.95 mL, 9.84 mmol) in dry tetrahydrofuran (45 mL). Additional Red-Al was added (in 2.95 mL aliquots) and reflux maintained until the reaction was complete (30 hours, total 12 eq. Red-Al). A mixture of di-tert-butyl 1,3-acetonedicarboxylate (10 g, 38.7 mmol), 3,5-heptanedione (6.5 g, 50.3 mmol) and sodium methoxide (2.7 g, 50.3 mmol) in

0 methanol (100 mL) was stirred at room temperature overnight. Methanol was removed via rotary evaporation and the resulting orange sludge was partitioned between diethyl ether (100 mL) and 10 % aqueous hydrochloric acid (100 mL). The separated aqueous layer was extracted with diethyl ether (50 mL x 2). The combined organic portions were washed with saturated aqueous sodium chloride  
5 (20 mL), dried over sodium sulfate, filtered through a pad of silica (20 mm x 40 mm) and concentrated in vacuo to yield a yellow oil (13.23 g, 97 %): <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 1.20 (t, 6H), 1.60 (s, 18H) 2.74 (q, 4H), 6.55 (s, 1H), 11.73 (s, 1H).

10 Step B: Di-tert-butyl 3,5-diisopropyl-2'-benzyloxy-4'-fluoro-1,1'-biphenyl-2,6-dicarboxylate

The title compound was prepared from the intermediate obtained in Step A by the methods described in Example 241, Steps B, C, and E. <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 1.15 (s, 18H), 1.27 (dd, J=5.15, 1.65 Hz, 12 H), 3.06 (m, 2H), 4.95 (s, 2H), 6.65 (m, 2H), 7.27 (m, 7H).

15 Step C: 3,5-Diisopropyl-2'-benzyloxy-4'-fluoro-1,1'-biphenyl-2,6-dicarboxylate

To a solution of 14.37 g (25.53 mmol) of the intermediate obtained in Step B in dichloromethane (150 mL) at 0°C was added trifluoroacetic acid (20 mL, 259.60 mmol). This reaction mixture was allowed to warm to room temperature  
20 overnight. The reaction mixture was concentrated to dryness and the residue was partitioned between diethyl ether and aqueous sodium hydroxide. The organic layer was removed, washed with aqueous sodium hydroxide and the two aqueous layers were combined. The combined aqueous layers were washed with diethyl ether (1x) then made acidic by addition of HCl (10%) and extracted with diethyl  
25 ether (3x). The combined organic layers were dried over magnesium sulfate, filtered and concentrated to yield an off-white solid. The crude product was taken directly to the next step without any further purification.

30 Step D: Dimethyl 3,5-diisopropyl-2'-benzyloxy-4'-fluoro-1,1'-biphenyl-2,6-dicarboxylate

The mixture was allowed to warm to room temperature. After stirring for 1 day the mixture was  
35 diluted with water and extracted with diethyl ether (3x). The combined extracts were washed with brine (1x), dried over magnesium sulfate, filtered and concentrated to yield an off-white solid. <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>): δ 1.22 (dd,

3,5-Diisopropyl-2-(thiophenylmethyl)-6-(hydroxymethyl)-4'-fluoro-1,1'-biphenyl

- 10 A suspension of Wang-resin (100 g, 1.09 mmol/g hydroxylated) was suspended in 1 L of a solution of 4N HCl in dioxane and gently stirred at room temperature for two days. After filtration, the chlorinated resin was washed 6 times with each of the following solvents; dioxane, isopropanol and finally THF. The resin was then dried at 60°C overnight. From this resin, 2.5 g (2.2 mmol based on the chlorine content detected by elemental analysis) was suspended in DMF (25 mL) and stirred at room temperature for 5 minutes, then the DMF was decanted off for the addition of a solution of 3,5-diisopropyl-2-hydroxymethyl-6-carboxymethyl-4'-fluoro-1,1'-biphenyl (Example 244, Step D) (1.13 g, 3.3 mmol) in DMF (25 mL), followed by a solution of sodium hydride (60 % in mineral oil, 170 mg, 3.3 mmol) in DMF (12.5 mL). The suspension was stirred at room temperature for two days under an argon atmosphere. The suspension was then filtered and the resulting resin was successively washed 10 times with each of the following solvents; DMF, a mixture THF/water (1:1), THF and finally with CH<sub>2</sub>Cl<sub>2</sub>.
- 20 The resin residue was then treated with a solution of lithium aluminum hydride (1 M in THF, 15 mL, 15 mmol) and heated at reflux for 2 days. The suspension was filtered and the resulting residue was washed successively 10 times with each of the following solvents; THF, a mixture of THF/water (1:1), a mixture of THF/water (2:1), THF and finally with CH<sub>2</sub>Cl<sub>2</sub>.
- 25 The residue was suspended in THF (25 mL) and slowly treated with PBr<sub>3</sub> (835 µL, 8.7 mmol) at room temperature. The resin was filtered out and washed 10 times with each of the following solvents; THF, mixture of THF/1N sodium bicarbonate (1:1), THF/water (1:1), THF and finally CH<sub>2</sub>Cl<sub>2</sub>, then dried at 60°C overnight which afforded 2.25 g of resin (0.62 mmol/g based on the bromine content detected by elemental analysis).
- 30

- 0 To 25 mg of this intermediate coupled with a resin was added thiophenol (26.4 mg, 0.24 mmol) in dry THF (500  $\mu$ L) and N-methylmorpholine (26  $\mu$ L, 0.24 mmol), then the suspension was refluxed for 8 hours. After filtration, the resin was washed successively 10 times with each of the following solvents; THF, a mixture of THF/water (1:1) and THF. The resin was then suspended in a mixture of TFA and
- 5  $\text{CH}_2\text{Cl}_2$  (1:1) and stirred at room temperature for one hour. The resin was filtered off and the solvent recovered then evaporated. The residue was dissolved in a mixture of methanol and acetonitrile (1:1) and one drop of diisopropylethylamine, then stirred for one hour; HPLC: 12.5 min (Hypersil BDS-C18, 5 $\mu$ m, 125 x 2 mm/Hewlett Packard, Flow 0.5 mL, 0-13 min 30-90°C, 13-15 min 90°C, Solvent A: Water/0.1% TFA; Solvent B: Acetonitrile). After evaporation of the solvent, the
- 10 remaining residue was transferred in a microtiterplate for testing.

10 The pharmaceutical utility of compounds of this invention is indicated by the following assay for glucagon receptor activity.

The affinity for the glucagon receptor of compounds of the present invention is determined by the glucagon receptor binding assay. Membranes were prepared from Chinese Hamster Ovary cells expressing the glucagon receptor (CHO-HGR) by scraping the cells into hypotonic lysis buffer (10 mM Tris, pH 7.4, 2 mM EDTA, 5 mM MgCl<sub>2</sub> and 1 mM PMSF) and subjecting the material to Polytron homogenization. Nuclei were removed by a 15-min 800 x g centrifugation step conducted at 4°C. Membranes containing the receptor were collected by centrifugation at 15,000 x g for 15 min at 4°C. The membranes were washed once in lysis buffer and suspended in 0.25 M sucrose, 10 mM Tris, 5 mM EDTA, pH 7.4. The membranes were used in ligand binding studies as reported (Yoo-Warren, H., Willse, A.G., Hancock, N., Hull, J., McCaleb, M., and Livingston, J. Regulation of Rat Glucagon Receptor Expression. *Biochem. Biophysical Res. Commun.* **1994**, 205, 347-353). In brief, 10 ug of membrane protein was incubated in 130  $\mu$ l of binding buffer that consisted of 20 mM Tris, pH 7.4, 1 mM EDTA, 1 mg/ml BSA, and 1 mg/ml bacitracin. The membrane suspension was placed in each well of a 96-well filtration plate (glass fiber type C, Millipore). Twenty  $\mu$ l of test compound was added to each well to give final concentrations ranging from 2 nM to 20  $\mu$ M. Following the addition of test compound, 50  $\mu$ l of <sup>125</sup>I-glucagon (9 fmol) (NEN) was added to each well. Control wells contained membranes, 0.5% DMSO (solvent for test compounds), radiolabeled glucagon without and with excess native glucagon (1  $\mu$ M) to establish nonspecific binding. The plates were incubated for 60 min at room temperature, and then filtered on a Millipore vacuum apparatus. Following a wash step with ice-cold PBS/0.1% BSA, the filters were punched into test tubes, and the membrane bound radioactivity was determined. An IC<sub>50</sub> value (the concentration of test compound needed to reduce membrane binding of radiolabelled glucagon by 50%) was calculated for each compound. If 20  $\mu$ M

- 0 compound did not reduce glucagon binding by 50%, the % reduction at 20  $\mu$ M was reported in place of an IC<sub>50</sub> value. The binding characteristics for compounds of this invention are shown in Table I(C).
